# **Problem 1: Relational Model and SQL (18 points)**

坐号.

老牛姓夕.

Following are the relational schemas of a SRTP (Student Research Training Program) project database.

```
student (<u>sId</u>, sName, dId)
teacher (<u>tId</u>, tName, dId)
department (<u>dId</u>, dName)
project (<u>pId</u>, pName, tId, startTime, endTime)
participate (<u>pId</u>, <u>sId</u>, role)
```

The underlined attributes are primary keys, and foreign keys are listed as follows:

- "dId" in "student" references "department";
- "dId" in "teacher" references "department";
- "tId" in "project" references "teacher";

"pId" and "sId" in "participate" reference "project" and "student", respectively. In "participate", only two different roles are permitted: "leader" and "member". Based on the above relational schemas, please answer the following questions:

- (1) Write a relational algebra expression to find the names of the projects that are instructed by a teacher from the department "Computer Science". (4 points)
- (2) Write SQL statements to create tables project and participate with all the necessary

- constraints (Note: Tables student, teacher, and department have already been created and can be referenced). (6 points)
- (3) Write a SQL statement to find the names of the teachers that instruct at least one project started in the year 2020. (4 points)
- (4) Write a SQL statement to find the names of the students participating more than 2 projects. (4 points)

#### **Answers of Problem 1:**

```
(1)
\prod_{pName}(project \bowtie teacher \bowtie (\sigma_{dName="Computer Science"}(department))
(2)
CREATE TABLE project
     (pId char(10),
     pName varchar(20),
     tId char(10),
     startTime date,
     endTime date,
     primary key (pId),
     foreign key (tId) references teacher);
CREATE TABLE participate
     (pId char(10),
     sId char(10),
     role varchar(20),
     primary key (pId, sId),
     foreign key (pId) references project,
     foreign key (sId) references student,
     check (role="leader" or role="member"));
(3)
select distinct tName
from project, teacher
where project.tId=teacher.tId and startTime between '2020-01-01' and '2020-12-31'
(4)
select sName
from student
where sId in
     (select sId
     from participate
     group by sId
     having count(pId) > 2)
```

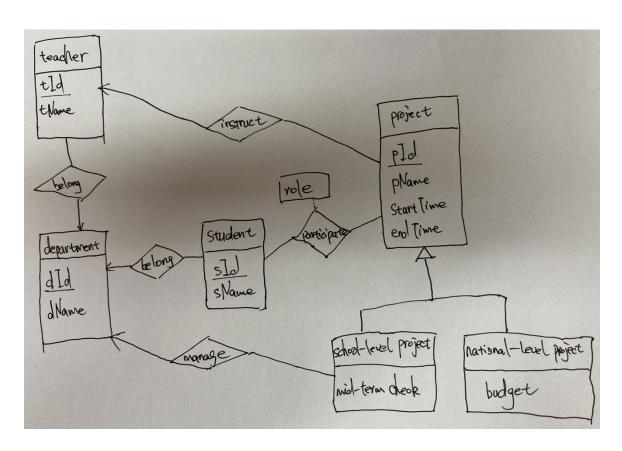

## **Problem 2: E-R Model (11 points)**

Based on the SRTP project management scenario in Problem 1, some new requirements are added as follows:

- (1) There are two kinds of SRTP projects, i.e., school-level projects and national-level projects, and a project is either school-level or national-level.
- (2) National-level projects have budget information, and school-level projects have midterm check information.
- (3) A school-level project is associated with exactly a department that is in charge of the management of the project.

Please draw an E-R diagram for the scenario.

#### **Answers of Problem 2:**

## **Problem 3: Relational Formalization (12 points)**

For relation schema R (A, B, C, D, E, F) with functional dependencies set  $F = \{A->B, A->C, B->C, D->E, D->F, EF->D\}$ . Answer the following questions:

- (1) Find all the candidate keys. (3 points)
- (2) Find the canonical cover Fc. (3 points)
- (3) If R is not in BCNF, decompose it into BCNF schemas. (4 points) Is this decomposition dependency preserving? (2 points)

#### **Answers of Problem 3:**

**(1)** 

AD AEF

(2)

(3)

There are different decomposition results and the following is just an example.

This decomposition is not dependency preserving (e.g., B->C is not preserved).

Following is another solution:

This decomposition is dependency preserving, because A->B can be checked on R21, B->C can be checked on R1, D->EF and EF->D can be checked on R221.

# Problem 4: XML (8 points)

The following is a simplified DTD for the SRTP project database given in Problem 1:

```
<!DOCTYPE
              SRTP[
   <!ELEMENT
                  SRTP(department+, teacher+, student+, project*)>
   <!ELEMENT
                  department (dname)>
                  department dId ID #REQUIRED>
   <!ATTLIST
                  teacher (tname)>
   <!ELEMENT
   <!ATTLIST
                  teacher
          tId ID #REQUIRED
           dId IDREF #REQUIRED>
   <!ELEMENT
                  student (sname)>
   <!ATTLIST
                  student
          sId ID #REQUIRED
          dId IDREF #REQUIRED>
                  project (pname, starttime, endtime)>
   <!ELEMENT
   <!ATTLIST
                  project
          pId ID #REQUIRED
          tId IDREF #REQUIRED
          sIds IDREFS #REQUIRED >
```

```
<!ELEMENT dname (#PCDATA)>
<!ELEMENT tname (#PCDATA)>
<!ELEMENT sname (#PCDATA)>
<!ELEMENT pname(#PCDATA)>
<!ELEMENT starttime(#PCDATA)>
<!ELEMENT endtime(#PCDATA)>
]>
```

Please answer the following questions:

- (1) Give an XPath expression to return the names of all the teachers who supervise SRTP projects. (4 points)
- (2) Give an XQuery expression to return all the projects and their corresponding instructors, in the form of project\_instructor elements that have a project subelement and a teacher subelement. (4 points)

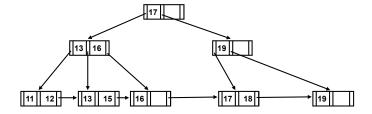

#### **Answers of Problem 4:**

```
(1)
/SRTP/project/id(@tId)/tname/text()
(2)
for $p in /SRTP/project,
$t in /SRTP/teacher,
where $p/@tId= $t/@tId
return <project instructor> { $p $t } </project instructor>
```

# **Problem 5: B+-Tree and Query Processing (10 points)**

Table student in Problem 1 is stored sequentially on sId. The following B+-tree is built for the table on attribute dId. Please answer the following questions:

- (1) Is the built index a primary index? Why? (2 points)
- (2) Draw the B+-tree after inserting entry 14. (4 points)
- (3) Draw the B+-tree after deleting entry 19 from the original B+-tree. (4 points)

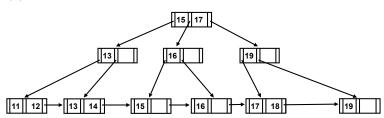

# **Answers of Problem 5:**

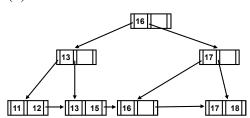

(1)

The built index is not a primary index, as the search key of the index is not the search key of the sequentially ordered data file.

(2)

## **Problem 6: Query Processing (14 points)**

There are two relations r (100 blocks) and s (20 blocks), and hash-join algorithm is used to perform natural join between these two relations (memory size M=6 blocks). Please answer the following questions:

- (1) How many partitions can be constructed? Why? (3 points)
- (2) Which relation is best to choose as the build relation? Why? (3 points)
- (3) Is recursive partition needed? Why? (3 points)
- (4) Please compute the cost (numbers of seeks and block transfers) of the hash-join. (5 points)

#### **Answers of Problem 6:**

**(1)** 

5 partitions, as the number of partitions is M-1.

(2)

Relation s, as relation s is smaller than relation r.

(3)

Recursive partition is not needed, as the size of the partitions of relation s (i.e., 4) is less than or equal to M-2 (i.e., 4).

(4)

Number of block transfers:  $3 \times (100+20)+4 \times 5$ 

Note:  $4 \times 5$  is not necessary, which considers partially filled blocks.

Number of seeks:  $2\times(100+20)+2\times5$ 

- If recursive partitioning is not required: cost of hash join is  $3(b_{\ell} + b_{s}) + 4 * n_{h}$  block transfers +  $2(\lceil b_{\ell}/b_{b} \rceil + \lceil b_{s}/b_{b} \rceil)$  seeks
- If recursive partitioning required:
  - number of passes required for partitioning build relation s to less than M blocks per partition is  $\lceil log_{Mbb} \mid 1(b_s/M) \rceil$
  - best to choose the smaller relation as the build relation.
  - · Total cost estimate is:

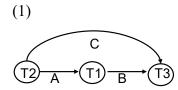

$$2(\underline{b}_{\ell} + \underline{b}_{s}) \lceil \underline{log}_{\lfloor Mbb \rfloor - 1}(\underline{b}_{s}/M) \rceil + \underline{b}_{\ell} + \underline{b}_{s} \text{ block transfers } + 2(\lceil \underline{b}_{\ell}/b_{b} \rceil + \lceil \underline{b}_{s}/b_{b} \rceil) \lceil \underline{log}_{\lfloor Mbb \rfloor - 1}(\underline{b}_{s}/M) \rceil \text{ seeks}$$

- If the entire build input can be kept in main memory no partitioning is required
  - Cost estimate goes down to b<sub>ℓ</sub> + b<sub>s</sub>.

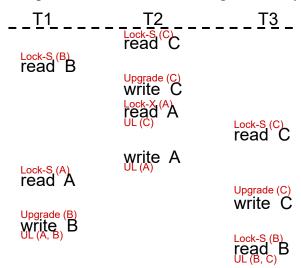

# **Problem 7: Concurrency Control (13 points)**

Given the following schedule, please answer	T1	T2	Т3
the following questions:		read C	
(1) Draw the precedence graph for the	read B		
schedule. (3 points)		write C	
(2) Is the schedule conflict serializable?		read A	
Why? (2 points)			read C
(3) Is it possible that the schedule is		write A	
generated by the 2PL protocol with lock	read A		
conversions? Explain. (5 points)			write C
(4) Which conditions should be satisfied if	write B		
we want the schedule to be recoverable?			read B
(3 points)			

# **Answers of Problem 7:**

- (2) The schedule is conflict serializable, as the precedence graph is acyclic.
- (3) It is possible that the schedule is generated by the 2PL protocol with lock conversions.

(4)

T1 must commit before T3 does.

T2 must commit before T1 does.

T2 must commit before T3 does.

## **Problem 8: Recovery (14 points)**

Given the following log file that supports logical undo, please answer the following questions:

- (1) The system crashes just after the last log record. What are the values of B and C in the database after system crash? (3 points)
- (2) Which transactions should redo and undo, respectively? (3 points)
- (3) What are the start and end points for redo and undo, respectively? (3 points)
- (4) What are the log records added during recovery? (5 points)

```
<T<sub>0</sub> start>
2
      <T<sub>0</sub>, B, 2000, 2050>
3
     <T<sub>1</sub> start>
4
     <T<sub>1</sub>, B, 2050, 2100>
5 < T_1, O_1, operation-begin>
6 <checkpoint \{T_0, T_1\}>
7
     <T<sub>1</sub>, C, 700, 400>
8 \langle T_0 \text{ commit} \rangle
9 \langle T_1, O_1, \text{ operation-end, } (C, +300) \rangle
10 < T_2 \text{ start} >
11 <T<sub>2</sub>, O<sub>2</sub>, operation-begin>
12 <T<sub>2</sub>, C, 400, 300>
13 <T<sub>2</sub>, O<sub>2</sub>, operation-end, (C, +100)>
14 \langle T_2, \text{ commit} \rangle
```

#### **Answers of Problem 8:**

```
(1)
B=2100
C= 300 or 400 or 700

(2)
redo: T<sub>0</sub> and T<sub>2</sub> undo: T<sub>1</sub>

(3)
redo: 7-14 undo: 14-3

(4)
<T<sub>1</sub>, C, 600>
<T<sub>1</sub>, O<sub>1</sub>, operation-abort>
<T<sub>1</sub>, B, 2050>
<T<sub>1</sub>, abort>
```
